Sales Dashboard

This project uses a fictitious sales dataset from different branches in Nigeria to demonstrate how business performance can be analyzed in Power BI. The data includes transaction details such as branch, product sold, price, quantity, sales time, and time ranges **(before and after 9am)**. The analysis explores overall sales performance, branch contributions, and product-level results against daily and product targets. It also highlights trends over the two-week period to support decision-making and provide insights into sales patterns.

Power BI Data Model for Sales Analysis

This data model shows how all the tables in the project are connected to give a complete view of sales performance. The Sales Data table is the main fact table because it stores the actual sales transactions such as branch, pizza sold, date, price, quantity, and time. The Branch Data table is linked to it to provide details about each branch like location and manager. The Sales Target table is connected to show the sales goal for each product so we can compare actual performance against targets. The Daily Sales Target table contains the daily targets and is connected with the Date table to check whether sales are meeting the goals each day. The Date table acts as a calendar and allows analysis by year, month, weekday, and day. Together these tables create a star schema where the Sales Data is at the center, making it easy to analyze sales by time, branch, and product while also comparing results to targets.

Excel Analysis

Before building my Power BI dashboard, I first analyzed the raw sales data in Excel. I highlighted my calculations in yellow so it is easy to follow. In Excel I worked out the sales performance by branch, including total sales, orders, quantities, contribution percentage and the average order value for each branch. I also compared sales targets and actual sales for each product, showing the variance and achievement percentage. I did the same for daily sales performance, comparing the daily targets with the actual sales to see which days fell short or performed better. Finally, I split the sales into before 9am and after 9am to see how the time of the day affected sales.

This Excel analysis gave me a clear understanding of the data and allowed me to check the calculations before moving into Power BI, where I created the dashboard to show the insights visually.
